To get an idea, it needs foliar fertilization, in addition to conventional fertilization, so that it can receive microelements. It is a fertilization procedure that must be carried out between stages V6 and V8, which represent the phases in which the plant has 6 and 8 leaves.

Soil Preparation – The most suitable type of planting for wheat silage is no-till, as it allows soil moisture to be maintained. A better planned structure and better compaction. To perform no-tillage it is recommended to have knowledge about green cover for each type of region, specific planters, as well as drying methods.

Harvesting the silage – The harvesting process for wheat silage involves a series of operations, among which are: cutting the crop plants, chopping these plants, unloading the plants, in addition to unloading them in their proper silos.
